Ennis-Weir Results Review

Fine-tuned Qwen2.5-0.5B-Instruct | 14 October 2026

Finding: this run demonstrates some successful critical-thinking behaviors, but unreliable overall evaluation of arguments. The model sometimes notices insufficient evidence or alternative explanations. It also invents details, misses decisive flaws, and gives contradictory judgments.

Reviewed: all four scenario responses, all 21 scoring units, and all 18 paragraph error groups. This is one AI-assisted review of one greedy evaluation round, with no independent human rating yet.

Scenario	Base credit / max	Capped deductions	Primary net
Moorburg parking letter	0 / 29	9	-9
Air pollution	6 / 15	3	3
Clothing store	6 / 12	3	3
Electric bicycles	3 / 9	3	0
Total	15 / 65	18	-3

How to read -3: the project first gives 15 points for reference-aligned insights and then deducts 18 points for paragraphs containing material errors. Its predeclared policy does not floor scores at zero. The result is a rubric point total, not an accuracy percentage, probability, or negative ability.

Eight of the 21 scoring units receive some credit; two receive full three-point credit. Both full-credit observations occur in essays that also contain separately documented mistakes.

Positive examples: recognizing that a six-customer sample cannot support population-level claims; considering transportation and other contributors to city pollution. **Serious gaps:** missing the equal 50% survey proportions, the afternoon-versus-overnight time mismatch, and the difference between charging battery risks and street use.

The linked TSA result remains **10/35 (28.6%)**. TSA accuracy and EW rubric points measure different task outcomes and are reported separately. They are not added into a new capability score.

Scoring rules and formulas

The author-released manual gives reference-alignment credit: 0 for unrelated content, 1-2 for incomplete recognition, and 3 for a complete criterion match. The original closing evaluation has four components worth 1 + 1 + 2 + 1 = 5 points. Equivalent wording is accepted.

A correct generic label such as “weak” is insufficient when its explanation does not identify the relevant weakness. Valid partial critiques receive credit even if another part of the same response contains an error; those errors are documented separately. This prevents discarding real strengths or letting a plausible-sounding explanation hide a mistake.

Base credit: B = sum of b(i), across 21 scoring units. Here B = 15; maximum = 65.

Primary deductions: D(manual) = sum of min(1, e(p)), across 18 paragraph groups.

Primary score: S(manual) = B - D(manual) = 15 - 18 = -3.

b(i) is the assigned reference-alignment credit. e(p) is the number of documented material error instances in a response paragraph, including the explicit missing-scope deductions for original paragraphs 3 and 8. The cap prevents two flaws within one paragraph from receiving duplicate primary deductions.

Article-wording sensitivity: S(article) = B - sum of e(p) = 15 - 34 = -19.

The paper says one deduction per error instance; the released manual caps deductions at one per paragraph. This report therefore preserves the manual-based primary result and labels the per-error calculation as sensitivity. Error-instance segmentation is judgment-dependent; -19 is not a second independent test or a directly equated publication score. [1, 2]

Scenario	Documented errors	Sensitivity net
Original	20	-20
Air pollution	5	1
Clothing store	5	1
Electric bicycles	4	-1
Total	34	-19

No deductions were assigned for grammar, style, headings, repetition alone, or absent thinking tags. Repeated versions of the same erroneous claim within a paragraph count once. The same claim repeated in separately requested paragraph evaluations is documented in each evaluation. Non-required omissions usually reduce alignment credit without adding an omission penalty.

Run completion and evidence integrity

The response logs preserve the complete released prompts. Each scenario was evaluated in its own fresh chat. All four responses ended with an end token; none hit the 2,048-token output budget. The recorded inputs were below the 2,048-token input setting. The visible problems therefore do not appear to be explained by an interrupted or budget-limited response.

Scenario	Input tokens	Output tokens	Finish	Seconds
Moorburg parking letter	922	1269	eos	330.634
Air pollution	466	1121	eos	251.488
Clothing store	483	704	eos	160.920
Electric bicycles	397	845	eos	197.701

Total inference time: **940.743 seconds (15 minutes 40.743 seconds)**. Ending naturally confirms generation completion; it does not mean the model fulfilled the task or produced sound judgments.

Recorded setting	Value
Base model	Qwen/Qwen2.5-0.5B-Instruct
Adapter	qwen_lora/best
Generation	Temperature 0; greedy; one round
System prompt	detailed thinking on
Execution	CPU; float32; four threads
Context capacity	32,768 tokens
Libraries	PyTorch 2.14.1+cpu; Transformers 4.57.6; PEFT 0.18.1
Reference answers	Held out of model prompts

The saved code fingerprints match the evaluator used for this review. The material bank matches the pinned source release. The saved base revision and adapter fingerprints match the earlier TSA run. This supports describing both components as evaluations of the same recorded configuration.

The completed ratings retain the exact uploaded run-configuration and response-file hashes. Every explicit evidence excerpt was validated against the corresponding raw response. The scorer validated all 21 ratings and 18 error groups and rebuilt a complete reviewed summary without running model inference. These checks establish provenance and arithmetic, not the correctness of subjective grading decisions.

Original letter: paragraphs 1-3

Scores below are base credit before paragraph-level error deductions. The full original response was inspected, including its final unnumbered closing heading.

EW-ORIGINAL-P1: 0 / 3 base points

Criterion: Identify the invalid parking/garage analogy, or the change in the legal meaning of garage.

*“1. **Legal Compliance**: The letter argues that nighttime parking is illegal under current laws. This aligns with the reasoning that nighttime parking is inherently illegal due to its impact on public safety.”*

Assessment: The expected critique is the invalid parking/garage analogy or change in the meaning of garage. The response instead endorses an unsupported legal inference and never identifies that flaw.

EW-ORIGINAL-P2: 0 / 3 base points

Criterion: Identify that banning parking at 2-6 a.m. cannot solve afternoon rush-hour congestion.

*“1. **Safety Risks**: The letter criticizes nighttime parking as potentially dangerous, citing instances where accidents occur despite the presence of night-time parking signs. This indicates a lack of trust in the effectiveness of nighttime parking regulations.”*

Assessment: A weak-argument heading is present, but the explanation does not identify the key time mismatch: a 2-6 a.m. ban cannot solve afternoon congestion. Its invented accidents/signs narrative is unrelated to that criterion.

EW-ORIGINAL-P3: 0 / 3 base points

Criterion: Recognize the plausible early-shift congestion argument, but limit its scope to affected streets.

*“**Closing Argument** The letter concludes by emphasizing the need for comprehensive solutions to address the issue of nighttime parking. It calls for a coordinated effort to implement stricter nighttime parking regulations, ensuring that nighttime parking remains a viable option while minimizing negative impacts on public safety and quality of life.”*

Assessment: The response does not explain why commuting to a 6 a.m. shift overlaps the proposed ban. It gives a generic conclusion instead of evaluating this argument and does not restrict the inference to affected streets.

Original letter: paragraphs 4-6

Scores below are base credit before paragraph-level error deductions. The full original response was inspected, including its final unnumbered closing heading.

EW-ORIGINAL-P4: 0 / 3 base points

Criterion: Identify circular reasoning: saying parking is bad supplies no independent reason to oppose it.

*“1. **Legality**: The letter acknowledges that nighttime parking is legal under current laws, but this reinforces the argument that nighttime parking is inherently illegal due to its adverse effects on public safety.”*

Assessment: The response calls the thinking good but does not identify circular reasoning or the absence of independent support. Its legal and traffic-flow claims are unrelated to the paragraph being evaluated.

EW-ORIGINAL-P5: 0 / 3 base points

Criterion: Identify the limited accident type, tradeoffs imposed by the ban, or alternative ways to prevent accidents.

*“1. **Safety Concerns**: The letter criticizes nighttime parking as potentially dangerous, pointing out incidents where accidents occurred despite the presence of night-time parking signs. This indicates a lack of trust in the effectiveness of nighttime parking regulations.”*

Assessment: The response does not identify the limited accident type, the burden/costs of the ban, or less restrictive accident-prevention alternatives. It attaches cost and space concerns to existing parking rather than explaining the consequences of prohibition. Generic weak labeling earns no substantive alignment credit.

EW-ORIGINAL-P6: 0 / 3 base points

Criterion: Challenge the one-day causal experiment, possible alternative causes, or missing relevant accident baseline.

*“**Closing Argument** The letter concludes by emphasizing the need for comprehensive solutions to address the issue of nighttime parking. It calls for a coordinated effort to implement stricter nighttime parking regulations, ensuring that nighttime parking remains a viable option while minimizing negative impacts on public safety and quality of life.”*

Assessment: No critique of the one-day experiment, alternative causes, or unknown proportion of nighttime parked-car accidents is provided. A repeated generic policy conclusion does not answer the criterion.

Original letter: paragraphs 7-9

Scores below are base credit before paragraph-level error deductions. The full original response was inspected, including its final unnumbered closing heading.

EW-ORIGINAL-P7: 0 / 3 base points

Criterion: Challenge the impossible zero-risk definition of safety or its self-defeating implications.

*“1. **Legality**: The letter acknowledges that nighttime parking is legal under current laws, but this reinforces the argument that nighttime parking is inherently illegal due to its adverse effects on public safety.”*

Assessment: No critique of the unrealistic zero-risk definition of safety, or its self-defeating implications for the ban, is provided. The response instead repeats an unrelated good-argument template.

EW-ORIGINAL-P8: 0 / 3 base points

Criterion: Recognize relevant expert recommendations, but note that they apply to busy streets rather than all streets.

*“1. **Safety Concerns**: The letter criticizes nighttime parking as potentially dangerous, pointing out incidents where accidents occurred despite the presence of night-time parking signs. This indicates a lack of trust in the effectiveness of nighttime parking regulations.”*

Assessment: The response does not recognize relevant expert authority or its limitation to busy streets. It labels the thinking bad using invented accident/sign claims rather than evaluating the cited recommendations.

EW-ORIGINAL-P9: 0 / 5 base points

Criterion: Evaluate the overall argument, summarize paragraph strengths/weaknesses, and detect scope and emotional-pressure issues.

“The letter concludes by emphasizing the need for comprehensive solutions to address the issue of nighttime parking. It calls for a coordinated effort to implement stricter nighttime parking regulations, ensuring that nighttime parking remains a viable option while minimizing negative impacts on public safety and quality of life.”

Assessment: The closing does not judge the total argument weak, summarize the six weak versus two relatively strong paragraphs, identify all-streets overgeneralization, or identify manipulative emotional wording. Its general call for coordination is not the required evaluation.

Closing component	Available	Awarded
Overall weak evaluation	1	0
Six weak / two relatively strong summary	1	0
Some-to-all streets overgeneralization	2	0
Manipulative emotional language	1	0

Air pollution: criterion-by-criterion review

Credit recognizes substantive alignment, including incomplete insights. It does not endorse the essay as a whole. Its errors are assessed separately.

EW-NEW-1-P1-F1: 3 / 3 base points

Criterion: Recognize other possible pollution sources or influencing factors.

“The mayor’s assertion that Shengda Chemical Plant is the main source of pollution could be seen as a simplification without considering other contributing factors such as industrial processes, transportation, and urban planning.”

Assessment: Explicitly identifies plausible other pollution contributors. The released criterion accepts identifying other influencing factors; this satisfies it. Separate unsupported assertions are deducted below.

EW-NEW-1-P1-F2: 1 / 3 base points

Criterion: Distinguish the highest-emitting plant from a plant responsible for most total emissions; its share is unknown.

“The mayor’s focus on Shengda Chemical Plant suggests that the issue is more complex than a single plant’s emissions alone.”

Assessment: Partially questions attribution to one plant. It does not identify the central missing quantity: its share of total emissions relative to other plants. Broad complexity language earns limited credit; human review is a priority.

EW-NEW-1-P2-F1: 2 / 3 base points

Criterion: Explain why historical contributions and cultural importance do not negate pollution responsibility.

“The employee representative’s argument assumes that Shengda Chemical Plant’s legacy and values are sufficient to mitigate the city’s air pollution.”

Assessment: Recognizes an invalid bridge from historical values to an environmental conclusion. Credit is partial because the source claims exemption from responsibility, not that heritage physically mitigates pollution; the response does not clearly state that contributions cannot cancel pollution responsibility.

EW-NEW-1-P3-F1: 0 / 3 base points

Criterion: Consider negative consequences of production cuts, such as economic harm.

“The mayor’s goal of improving air quality through stringent regulations is well-intentioned and aligns with the principles of sustainable development.”

Assessment: Does not identify negative consequences of compulsory production reduction, such as economic harm. Generic implementation/coordination concerns do not satisfy this criterion.

EW-NEW-1-P3-F2: 0 / 3 base points

Criterion: Consider cleaner processes/materials or other source-level alternatives without compulsory production cuts.

“The mayor’s proposal to establish strict emission standards for chemical plants is a practical and feasible solution.”

Assessment: Does not propose cleaner processes, materials, or comparable source-level alternatives that reduce pollution without requiring production cuts.

Clothing store: criterion-by-criterion review

Credit recognizes substantive alignment, including incomplete insights. It does not endorse the essay as a whole. Its errors are assessed separately.

EW-NEW-2-P1-F1: 3 / 3 base points

Criterion: Recognize that six interviewees cannot support a representative population-level conclusion.

“There could be a risk of overgeneralizing from the sample results to the entire population due to the small sample size and potential selection bias.”

Assessment: Correctly identifies small-sample generalization and representativeness concerns. Explicitly identifies the required weakness; failure to repeat the number six does not remove substantive credit.

EW-NEW-2-P1-F2: 0 / 3 base points

Criterion: Recognize equal proportions: 2/4 women = 1/2 men = 50%; the gender claim is unsupported.

“While the solution involves prioritizing female customers, it lacks a clear rationale for why these customers should receive special attention.”

Assessment: This questions the policy but does not recognize the equal proportions: 2/4 women and 1/2 men are both 50%. No explanation of the numerical comparison is provided.

EW-NEW-2-P2-F1: 2 / 3 base points

Criterion: Challenge renovation as the cause of higher sales, especially the National Day holiday confound.

“The absence of a control group and the use of only one week of data do not provide a robust basis for concluding that the decision was correct.”

Assessment: A valid partial challenge to causal attribution: the comparison cannot isolate renovation. It misses the known National Day holiday confound, so it does not fully identify the concrete alternative cause.

EW-NEW-2-P3-F1: 1 / 3 base points

Criterion: Recognize differences between winter clothing sold in summer and summer clothing sold in winter.

“The reliance on past performance alone does not guarantee future success.”

Assessment: A minimally relevant critique of transferring prior results. It does not identify the different clothing types, seasons, market demand, or unit prices that make these cases non-equivalent; therefore limited partial credit.

Electric bicycles: criterion-by-criterion review

Credit recognizes substantive alignment, including incomplete insights. It does not endorse the essay as a whole. Its errors are assessed separately.

EW-NEW-3-P1-F1: 1 / 3 base points

Criterion: Ask what share of city-center accidents involves electric bicycles before inferring a large ban effect.

“The argument assumes that electric bicycles cause accidents without considering other factors such as rider behavior, road conditions, and overall traffic flow.”

Assessment: Partially challenges an unestablished accident attribution by identifying other causes. It does not ask how many of the 100-plus accidents involved electric bicycles, or whether that share supports a large reduction, so only limited credit.

EW-NEW-3-P2-F1: 2 / 3 base points

Criterion: Distinguish correlation of rising purchases/accidents from proof of causation.

“The argument assumes that electric bicycles are responsible for traffic accidents without considering alternative explanations such as driver fatigue, poor road conditions, or lack of proper maintenance.”

Assessment: Identifies alternative explanations for the alleged causal connection. It does not explicitly explain why parallel increases in purchases and accidents are correlation rather than proof of causation; partial credit remains despite the separate contradictory strong verdict.

EW-NEW-3-P3-F1: 0 / 3 base points

Criterion: Challenge the bomb analogy and distinguish charging in buildings from riding on streets.

“The argument emphasizes the safety risks associated with electric bicycles, particularly regarding fire hazards.”

Assessment: Does not criticize the battery/bomb analogy or distinguish charging in residential buildings from riding on city-center streets. Generic traffic-safety concerns do not identify the required transfer error.

Error audit: original paragraphs 1-3

Each numbered entry below is one documented material error instance. The primary score deducts at most one point per paragraph group; the sensitivity calculation deducts each instance. Exact quotes and fuller explanations are preserved in paragraph_error_log.json.

Paragraph 1: 3 documented errors; primary deduction = 1

1. endorsed flawed argument

“This aligns with the reasoning that nighttime parking is inherently illegal due to its impact on public safety.”

Endorses the invalid legal analogy without showing that overnight parking is equivalent to constructing a garage.

2. unsupported claim

“The letter mentions that nighttime parking poses risks to drivers, pedestrians, and cyclists, leading to increased accidents and fatalities.”

The letter supplies no fatalities or pedestrian/cyclist accident evidence.

3. unsupported claim

“The letter cites data suggesting that nighttime parking is disliked by many residents, indicating widespread dissatisfaction with the status quo.”

No resident poll or dissatisfaction data is supplied.

Three documented material errors; primary deduction capped at one.

Paragraph 2: 2 documented errors; primary deduction = 1

1. unsupported claim

“The letter criticizes nighttime parking as potentially dangerous, citing instances where accidents occur despite the presence of night-time parking signs.”

The source reports zero accidents during the one-day sign experiment, not accidents despite signs. No such instances are supplied elsewhere in the letter.

2. faulty reasoning

“The letter concludes by stating that opposition to nighttime parking is based on fear of potential accidents, which is inconsistent with the letter’s primary argument that nighttime parking is inherently unsafe.”

Fear of accidents is not logically inconsistent with regarding parking as unsafe. The response also misreports the source, which calls for a ban rather than opposing parking out of fear.

Two documented material errors; correct weak heading does not repair unrelated explanations.

Paragraph 3: 2 documented errors; primary deduction = 1

1. scope omission

“Missing required qualification.”

The required qualification is missing: the early-shift congestion argument supports restrictions on affected streets, not all city streets.

2. unsupported claim

“It calls for a coordinated effort to implement stricter nighttime parking regulations, ensuring that nighttime parking remains a viable option while minimizing negative impacts on public safety and quality of life.”

The letter proposes eliminating overnight parking on all streets. The response invents a conclusion preserving nighttime parking as a viable option.

Scope qualification absent; record its required deduction once. The policy conclusion is also misreported.

Error audit: original paragraphs 4-6

Each numbered entry below is one documented material error instance. The primary score deducts at most one point per paragraph group; the sensitivity calculation deducts each instance. Exact quotes and fuller explanations are preserved in paragraph_error_log.json.

Paragraph 4: 3 documented errors; primary deduction = 1

1. endorsed flawed argument

*“**Reasons for Believing the Thinking Good**”*

In paragraph four, the response endorses a circular, unsupported argument as good and supplies no independent justification for it.

2. faulty reasoning

“The letter acknowledges that nighttime parking is legal under current laws, but this reinforces the argument that nighttime parking is inherently illegal due to its adverse effects on public safety.”

Acknowledging that conduct is legal does not establish that it is inherently illegal; public-safety concerns do not supply that inference.

3. unsupported claim

“The letter highlights that nighttime parking helps manage traffic flow, particularly during peak hours, thereby improving overall traffic efficiency and reducing congestion.”

The letter argues that parked cars obstruct traffic, not that nighttime parking improves traffic flow. The response reverses the supplied claim.

Three distinct errors: endorsement, contradictory legal inference, and reversed traffic claim.

Paragraph 5: 2 documented errors; primary deduction = 1

1. unsupported claim

“The letter criticizes nighttime parking as potentially dangerous, pointing out incidents where accidents occurred despite the presence of night-time parking signs.”

The source reports zero accidents during the one-day sign experiment, not accidents despite signs. No such instances are supplied elsewhere in the letter.

2. faulty reasoning

“The letter concludes by stating that opposition to nighttime parking is based on fear of potential accidents, which is inconsistent with the letter’s primary argument that nighttime parking is inherently unsafe.”

Fear of accidents is not logically inconsistent with regarding parking as unsafe. The response also misreports the source, which calls for a ban rather than opposing parking out of fear.

Two material errors. Missing the target tradeoff critique is handled through zero credit, not an extra omission deduction.

Paragraph 6: 1 documented errors; primary deduction = 1

1. unsupported claim

“It calls for a coordinated effort to implement stricter nighttime parking regulations, ensuring that nighttime parking remains a viable option while minimizing negative impacts on public safety and quality of life.”

The letter proposes eliminating overnight parking on all streets. The response invents a conclusion preserving nighttime parking as a viable option.

One material misrepresentation. Failure to analyze the experiment earns zero credit without another omission penalty.

Error audit: original paragraphs 7-9

Each numbered entry below is one documented material error instance. The primary score deducts at most one point per paragraph group; the sensitivity calculation deducts each instance. Exact quotes and fuller explanations are preserved in paragraph_error_log.json.

Paragraph 7: 3 documented errors; primary deduction = 1

1. endorsed flawed argument

*“**Reasons for Believing the Thinking Good**”*

In paragraph seven, the response calls the zero-risk safety argument good without addressing its unrealistic definition.

2. faulty reasoning

“The letter acknowledges that nighttime parking is legal under current laws, but this reinforces the argument that nighttime parking is inherently illegal due to its adverse effects on public safety.”

Acknowledging that conduct is legal does not establish that it is inherently illegal; public-safety concerns do not supply that inference.

3. unsupported claim

“The letter highlights that nighttime parking helps manage traffic flow, particularly during peak hours, thereby improving overall traffic efficiency and reducing congestion.”

The letter argues that parked cars obstruct traffic, not that nighttime parking improves traffic flow. The response reverses the supplied claim.

Three material errors in this separately requested evaluation.

Paragraph 8: 3 documented errors; primary deduction = 1

1. unsupported claim

“The letter criticizes nighttime parking as potentially dangerous, pointing out incidents where accidents occurred despite the presence of night-time parking signs.”

The source reports zero accidents during the one-day sign experiment, not accidents despite signs. No such instances are supplied elsewhere in the letter.

2. faulty reasoning

“The letter concludes by stating that opposition to nighttime parking is based on fear of potential accidents, which is inconsistent with the letter’s primary argument that nighttime parking is inherently unsafe.”

Fear of accidents is not logically inconsistent with regarding parking as unsafe. The response also misreports the source, which calls for a ban rather than opposing parking out of fear.

3. scope omission

“Missing required qualification.”

The required qualification is missing: the cited authorities recommend restrictions on busy streets, not every street.

Two explicit errors and the required missing busy-streets qualification. No separate penalty for the bad heading.

Paragraph 9: 1 documented errors; primary deduction = 1

1. unsupported claim

“It calls for a coordinated effort to implement stricter nighttime parking regulations, ensuring that nighttime parking remains a viable option while minimizing negative impacts on public safety and quality of life.”

The letter proposes eliminating overnight parking on all streets. The response invents a conclusion preserving nighttime parking as a viable option.

One material misrepresentation in the total-argument evaluation. Missing closing components are scored through zero credit.

Error audit: Air pollution

Each numbered entry below is one documented material error instance. The primary score deducts at most one point per paragraph group; the sensitivity calculation deducts each instance. Exact quotes and fuller explanations are preserved in paragraph_error_log.json.

Paragraph 1: 3 documented errors; primary deduction = 1

1. unsupported claim

“Shengda Chemical Plant, which is an outlier in terms of emissions compared to other chemical plants.”

Having the highest emissions does not establish that a plant is an outlier; no distribution or magnitude gap is supplied.

2. unsupported claim

“The mayor’s view that Shengda Chemical Plant is the primary culprit is likely influenced by his personal connections and the prominence of the plant in the city’s history.”

Personal connections between the mayor and the plant are invented, with no source evidence.

3. unsupported claim

“The mayor’s proposed solution focuses solely on reducing emissions from Shengda Chemical Plant.”

The first paragraph establishes an investigation and attribution of blame, not this policy. The later actual policy applies to all chemical plants. The same error repeated in the extra conclusion is not charged again.

Three material errors, one primary deduction. Valid alternative-source critique still earns full base credit.

Paragraph 2: 1 documented errors; primary deduction = 1

1. unsupported claim

“The representative’s proposal to establish stricter emission standards for chemical plants”

The mayor, not the factory employee representative, proposes emissions standards. This mixes up the speakers and their positions.

One misattribution; partial irrelevant-evidence recognition is preserved.

Paragraph 3: 1 documented errors; primary deduction = 1

1. unsupported claim

“It addresses the root causes of the problem by addressing the underlying issues related to industrial emissions and transportation.”

Standards and production reductions for chemical plants do not, as specified, address transportation emissions.

One policy-scope misrepresentation. Missing costs and alternatives earn zero credit without extra omission penalties.

Error audit: Clothing store

Each numbered entry below is one documented material error instance. The primary score deducts at most one point per paragraph group; the sensitivity calculation deducts each instance. Exact quotes and fuller explanations are preserved in paragraph_error_log.json.

Paragraph 1: 1 documented errors; primary deduction = 1

1. unsupported claim

“Xiao Wu conducted a controlled experiment using random sampling to test his hypothesis. This method ensures that any observed differences can be attributed to the treatment rather than other factors such as gender or time of day.”

The source describes a six-person interview, not a controlled treatment experiment. Randomly selecting interviewees cannot ensure causal attribution or control other factors. These are one linked erroneous experiment claim.

One linked design/causal-attribution error; the valid small-sample critique receives separate credit.

Paragraph 2: 2 documented errors; primary deduction = 1

1. unsupported claim

“By tracking sales data over several weeks, he was able to identify patterns and make informed decisions based on statistical analysis.”

The source supplies only one week after renovation and a comparison with the previous week, not several weeks of pattern tracking/statistical analysis.

2. endorsed flawed argument

“While the decision itself was successful, it lacked a comprehensive plan to ensure repeatable success.”

The observed sales rise does not establish that renovation was successful as its cause. The response also calls the causal argument strong despite separately recognizing missing controls. Count these as one unsupported causal-success endorsement.

Two errors: invented duration/analysis and unsupported causal-success endorsement.

Paragraph 3: 2 documented errors; primary deduction = 1

1. unsupported claim

“The conclusion that the prediction was accurate despite the lack of historical data is based on a flawed logic.”

The source explicitly supplies historical summer-sales data. Claiming no historical data fabricates a missing premise.

2. unsupported claim

“While the prediction itself was successful, it lacked a detailed plan to ensure repeatable success.”

The winter prediction has not yet been tested in the source. Calling it accurate/successful invents a future outcome; those phrasings are counted as one instance.

Two material errors. Generic skepticism about extrapolation receives limited credit.

Error audit: Electric bicycles

Each numbered entry below is one documented material error instance. The primary score deducts at most one point per paragraph group; the sensitivity calculation deducts each instance. Exact quotes and fuller explanations are preserved in paragraph_error_log.json.

Paragraph 1: 2 documented errors; primary deduction = 1

1. endorsed flawed argument

“The argumentation is strong because it presents a clear causal relationship between electric bicycles and traffic accidents.”

The scenario supplies possible mechanisms and an overall accident total, but not the bicycle-related share needed to establish a large ban effect. Calling the inference a clear causal relationship overstates the evidence.

2. invented flaw

“nor does it account for the possibility of increased traffic congestion caused by electric bicycles.”

The source already discusses crowded non-motorized lanes and crossings into motorized lanes. Claiming congestion is not considered invents a missing consideration; repeated broader omission wording counts once.

Two material errors; partial alternative-cause recognition is credited separately.

Paragraph 2: 1 documented errors; primary deduction = 1

1. endorsed flawed argument

“The argumentation is strong because it presents a clear causal relationship between electric bicycles and traffic accidents.”

Two rising trends do not establish causation. The response explicitly calls this a clear causal relationship while also listing alternative explanations.

One unsupported causal-certainty endorsement. The first-paragraph congestion deduction is not copied here because this source paragraph concerns trends.

Paragraph 3: 1 documented errors; primary deduction = 1

1. invented flaw

“The argument assumes that electric bicycles are inherently unsafe without considering the inherent dangers of electric bicycles, such as the risk of electrical shocks or explosions.”

The source already emphasizes battery fire/explosion risk. Alleging that it fails to consider danger is unsupported, and ignoring dangers would not explain why the unsafe conclusion is invalid. Count this linked fabricated/illogical flaw once.

One linked fabricated flaw. The missed charging-versus-riding distinction earns zero credit without another omission penalty.

What you can conclude and present

The two fully credited insights provide behavioral evidence that this configuration can sometimes perform a useful critical-thinking move: it questions sample adequacy and considers other possible causes. The partial credits provide weaker, incomplete examples. These observations matter even though the overall score is low.

The original essay repeatedly applies unrelated templates. The added scenarios are more responsive, but the model often notices a weakness and then calls the same argument strong. It also confuses speakers, invents evidence or outcomes, and misses decisive details. Therefore the evidence supports **inconsistent and limited demonstrated performance**, rather than reliable general critical thinking.

Suggested presentation statement: “Under a single-round adapted evaluation using Jiang et al.’s released Ennis-Weir materials, fine-tuned Qwen2.5-0.5B-Instruct earned 15 of 65 base alignment points and incurred 18 capped paragraph deductions, giving -3 rubric points. The essays contain some valid critiques, but repeated unsupported claims, missed flaws, and contradictory judgments show that argument evaluation was unreliable in this run.”

This does not prove that the model has no capacity for reasoning or critical thinking. It also does not establish that producing an explanation is sufficient evidence of sound reasoning. The quality of the connection between premises and conclusion must be checked; a fluent explanation can misrepresent premises or draw an invalid inference. Written responses cannot by themselves verify a faithful internal thought process.

The earlier TSA result of 10/35 supplies another task outcome, not a certificate that reasoning has already been established. Report both results, their actual strengths, and the same-model identity check. Do not claim that low parameter count or the small fine-tuning dataset caused these errors: that explanation needs a controlled comparison and training-data evidence.

Limits: one configuration, one greedy round, English public items, one AI-assisted reviewer, no human baseline, and no inter-rater reliability. The study used 70 TSA items, 150 rounds per model, and three trained raters; this project has 35 original TSA items and the complete EW material set under a reduced protocol. No human percentile, calibrated publication comparison, confidence interval, or universal pass/fail threshold is available. [1]

Have a knowledgeable human score independently before reading this review. Prioritize the six partial-credit items listed in the ratings metadata. Their boundaries involve judgment; the software checks arithmetic and provenance but cannot validate the semantic grading. Agreement or disagreement should be reported rather than hidden. Repeated greedy calls alone will not provide useful sampling variation. Independent rating is the next verification step.

Using the completed files and verifying sources

The reviewed bundle includes completed ratings, an item-by-item score table, a paragraph error log, the rebuilt summary and combined assessment, and a reviewed evidence packet containing the unchanged raw responses. The original upload is preserved.

Apply these ratings without generating responses again: place ratings_completed.json in results\ew_final, then run this command from your project root in the same environment as before:

```
python EW_Evaluation\evaluate_ew.py apply-review
--out "results\ew_final"
--ratings "results\ew_final\ratings_completed.json"
```

Enter the command as one line. It validates the ratings against the existing run and rebuilds the scoring exports. Keep your original run_config.json and responses.jsonl unchanged; the ratings will be rejected if they belong to a different run.

Two measures, two meanings: TSA accuracy is 10 / 35 x 100 = 28.6%. EW is a rubric score, S = B - deductions, here -3 points. A confusion matrix or F1 score is not required for these open-ended ratings because no justified categorical labels or binary capability threshold were defined.
